

WINDOW-LEVEL TOOL

Finder

Full-text search across all views, stored procedures, functions, and triggers — find every object whose definition contains a string you enter.

Who

WHO IT IS FOR

Developers performing impact analysis, audits, or bug hunts across a database's programmable code.

What

WHAT IT DOES

The Finder scans the full text of every view, stored procedure, function, and trigger for a string you type — a column name, a table, a magic number, a deprecated call — and lists each object that contains it, so you can jump straight to the SQL.

When

WHEN TO USE IT

Use it before renaming or removing a database element, when tracing where a value or routine is used, or when tracking down a bug in server-side code.

Where

WHERE TO FIND IT

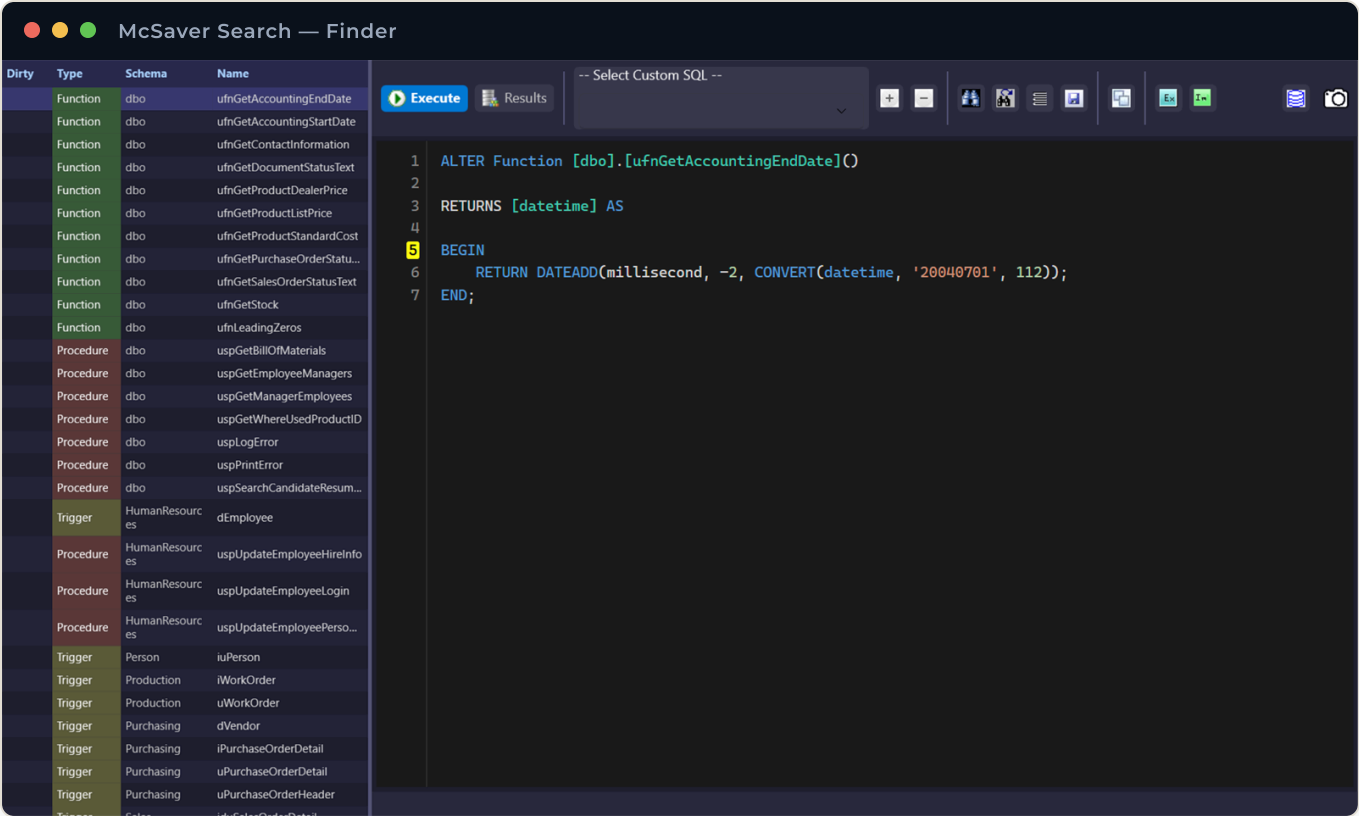

Open it from the Finder button in the Searcher header (a Pro feature). Enter a search string; matches are grouped by type and schema.

Why

WHY IT MATTERS

“Where is this used?” is one of the most common — and most error-prone — questions in database work. The Finder answers it across all SQL objects in seconds.
